### Understanding the perception of cities in society

Redaelli Tommaso, 830442, <u>t.redaelli7@campus.unimib.it</u> Merlo Riccardo, 829805, <u>r.merlo2@campus.unimib.it</u> Stoffa Giacomo, 830159, <u>g.stoffal@campus.unimib.it</u> Riva Leonardo, 830647, <u>l.riva37@campus.unimib.it</u>

### **Abstract**

Every city has its own special features: often people associates words that defines them. These **perceptions** can belong to different fields and can have positive or negative impact. This phenomenon often results in not-always-true **stereotypes**.

The goal is to analyze how the most **meaningful cities** can be **described** by society, with a focus on the links between them, highlighting what they have in common.

- Limitations and future research

### **COCA**

It is a large genre-balanced corpus of **contemporary american** english.

It is composed of 950 million words, evenly divided into categories, between 1990 and 2019.

academic

blogs & web pages tv & movies subtitles

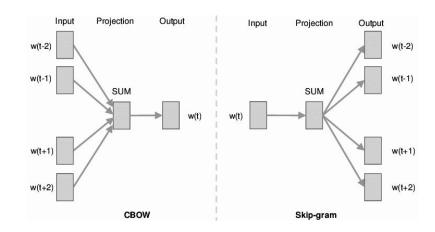

### Word2Vec

It is an algorithm to learn word associations from a corpus of text, in which each distinct word is represented with a vector.

**CBOW**: Predicts the **current word from a window** of surrounding context words no matter
the order (bag-of-words assumption).

**Skip Gram:** Uses the **current word to predict** the surrounding window of context words; close context words are weighted heavily than far context words.

### **WEAT**

Word-Embedding Association Test

It measures the **comparative polarization** between a pair of target words (X, Y) and a pair of polarization attributes (A, B) in a single-corpus distributional model

$$s(X,Y,A,B) = \sum_{x \in X} s(x,A,B) - \sum_{y \in Y} s(y,A,B)$$

$$s(w, A, B) = \text{mean}_{a \in A} \cos(\overrightarrow{w}, \overrightarrow{a}) - \text{mean}_{b \in B} \cos(\overrightarrow{w}, \overrightarrow{b})$$

The effect size is

$$\frac{\mathrm{mean}_{x \in X} s(x, A, B) - \mathrm{mean}_{y \in Y} s(y, A, B)}{\mathrm{std\_dev}_{w \in X \cup Y} s(w, A, B)}$$

## Corpus preprocessing

Use of the standard form, i.e. WLP.
Verbal tenses and plurals are not useful.

Reduction of composed tag PoS into their main form, e.g.  $nn_pp \rightarrow nn$ .

Lemmatization: only nouns [N], adjectives [J], adverbs [R] e verbs [V] are kept.

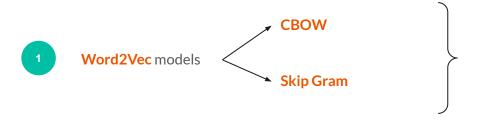

Bi-gram research, to fix composed words, according to the frequency at which two words appear together:

$$\frac{\ln \left(P(word_a, word_b)\right) / \left(P(word_a) \times P(word_b)\right)}{-\ln \left(P(word_a, word_b)\right)}$$

$$\text{where } P(word) = \frac{word\_count}{corpus\_word\_count}$$

$$\downarrow$$
"new york"
$$\rightarrow$$
"rio de janeiro"
$$\rightarrow$$
"rio janeiro"

## Model building and comparison

Built different models with both techniques, tuning parameters by following a trial-and-error pattern

Evaluation of the obtained models

For each model, we tested it on a predetermined list of analogies

Skip Gram performs better:  $SG\_mc50\_npmi \rightarrow acc. 0.602, std. 0.233$ 

CBOW\_mc50\_npmi  $\rightarrow$  acc. 0.543, std. 0.213

# **Step 1 -** Extract characterizing words for cities

1 How to represent the **collective imagination** of a city?

Subdivision of the entire image into different thematic areas (topic) [e.g. food, crime, environment, ....]

Given a city C and an area A, words are collected in order to describe C from the point of view of A. This process is then developed in two different methods, one "supervised" and one "unsupervised".

### Method 1: Supervised - Formulation

Idea: topics and their keywords are defined beforehand

```
crime = [abduction, terrorism, ...]
education = [high_school, learning, ...]
food = [restaurant, chef, ...]
work = [business, office, ...]
nightlife = [disco, theater, ...]
cold = [snow, winter, ...]
hot = [sun, summer, ...]
transport = [taxi, plane, ...]
environment = [ecology, sustainability, ...]
pollution = [waste, contamination, ...]
```

```
history = [king, castle, ...]
gambling = [roulette, blackjack, ...]
alcohol = [liquor, beer, ...]
music = [dance, k_pop, ...]
fitness = [healthy, workout, ...]
vegetation = [tree, florist, ...]
animals = [safari, zoo,...]
sport = [soccer, football, ...]
fashion = [hairdresser, stylist, ...]
tech = [technology, smartphone, ...]
```

## **Method 1: Supervised -** Algorithm & Results

To obtain words that best describe a city:

From the list of all words, find the closest ones in terms of cosine distance

Set upper limit on count & threshold on similarity, to filter meaningful words

#### **Examples**

- Nairobi → [bombing: 0.369, taxi: 0.338, safari: 0.291, ...]
- Athens → [ancient: 0.324, antiquity: 0.314, amphitheater: 0.293, ...]
- Sydney → [swimming: 0.383, rugby: 0.343, labour: 0.316,...]

### Method 2: Unsupervised - Formulation

1

**Basic idea:** given a city and a topic, analogies can be formulated to obtain words related to that specific city in that specific topic.

Example 1: city:crime = sao\_paulo:x

→ violent crime, homicide, carjacking, drug trafficking kidnapping, offender, commit crime, robbery, ...

Example 2: city:pollution = sao\_paulo:x

→ air\_pollution, carbon emission, ozone depletion, emission, ghg emission, deforestation, sulfur dioxide, ...

2

**Setting:** definition of the topics of interest, and, for each of them, some keywords that represent them

**crime**: [crime],

education: [education, school],
food: [food, recipe, alcohol],
sociality: [politic, economy],

tourism: [tourism, vacation], environment: [environment, pollution],

**history**: [history, folklore], **culture**: [music, dance, art].

**geo**: [vegetation, flora\_fauna]

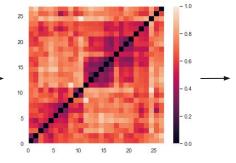

# Method 2: Unsupervised - Algorithm

Word collection: For each city, for each keyword of each topic, the words that should represent that characteristic in that city are obtained by analogy.

"city": keyword = city\_name:x

- min similarity threshold is set to 0.3, and limits to top 40 words
- due to noise, results that have no direct similarity with 'keyword' and 'city' > 0.2 are discarded
- Word clustering: To observe both the internal cohesion of a city and the degree of similarity between two of them, it may be useful to aggregate the list of terms obtained.

A DB-SCAN clustering is applied by placing the matrix of the distances – between the words collected as input.

#### "Crime" in Warsaw:

- 1. atrocity, tribunal hague, radovan karadzic
- 2. nazi, genocide, kristallnacht, auschwitz
- 3. katyn, nuremberg, espionage, nazism
- 1. ratko\_mladic, treblinka, mihailovic, pro\_nazi, gestapo, milosevic

## **Method 2: Unsupervised -** *Results*

- city: food = paris: x
  escargot, coq\_au, provencal, steak\_tartare, gourmet, cordon\_bleu, wine, hor, s'il\_plait, five\_course, gefilte\_fish, canape, bonbon
- city: crime = kinshasa: x
  rwanda, habyarimana, hutu, omar\_al\_bashir, tribunal\_hague, rwandan, violence, rwandan\_genocide, genocide, extrajudicial\_killing, war\_crimes, darfur
- city: history = athens: x
  thucydides, historical, historian, herodotus, egyptology, plato, peloponnesian, greek, aristotle, pericles, greco\_roman, epictetus

### Supervised vs. Unsupervised - Pro & cons

- The unsupervised method shows more specific and characteristic elements about cities, with a level of detail that the supervised method could not reach, unless the preset lists have not been enlarged enough (expensive). On the other hand, supervised results are more interpretable and reliable, as a result of a hand-made approach
- However, there's the problem of gathering too much general terms, not specific to cities, but common to several of them [e.g.  $environment \rightarrow climate\ change$ ], or even terms that are not entirely relevant to the area [e.g.  $food \rightarrow \langle kitchen\_book\_author \rangle$ ]
- Clusterization favors a future elaboration of unsupervised results but, on the other hand, being a partial clustering, it can prevent the identification of singular terms (i.e. unique words that do not have linked terms within those collected).

### WORKFLOW

#### o. Introduction

- 3.3. Method 2 Analogy
- 3.4. Results comparison

#### 4. Conclusion

- 4.1. Final results and stereotypes analysis
- 4.2. Limitations and future research

### **Step 2 -** Results representation

Two types of representations that show relationships between contents of different cities and distribution of the topics between cities.

#### WordCloud

The purpose is to show which are the most fit words to describe a city, emphasizing topic prevalence using colors.

#### Connection graph

The purpose is to observe how cities are positioned relatively to a specific area of interest, allowing to understand similarity relationships between them, as well as differences in predominance and cohesion of topics.

### Wordcloud

As in [3], cities are represented in word clouds, with a score:

- The **bigger** the word, the **more similar** to the city (cosine similarity to the city, with a threshold)
- The color represents the topic
- The score determines how much the topics are meaningful in representing a city
  - Inversely proportional to the number of topic
  - Directly proportional to the number of words of each topic

It is calculated as a product of absolute and relative frequencies of words and topics

## **Network graph**

**Idea:** represent the data for each topic through a graph.

- $\rightarrow$  **nodes** = cities
- → edges = connections between the content of their topics

Cities can be seen under many shades: for topic predominance, for internal cohesion or for different level of connection.

Node size: how much that city is close to the topic:

$$Dim = \frac{n^{\circ} of topic words}{n^{\circ} of total words}$$

**Node color:** different for each topic; its intensity is proportional to the cohesion between the words of that city

$$Color = \sum_{c=0}^{\dim(CL)} Cohesion(CL_c) \cdot Freq(CL_c)$$

# **Network graph**

Level of connection between two cities is given by the distance between the two mean vectors of the two cities.

#### Connection with Bogotà in Crime

- 3.4. Results comparison

#### 4. Conclusion

- 4.1. Final results and stereotypes analysis
- 4.2. Limitations and future research

### **Step 3 -** Results interpretation

The two representations already allow a meaningful exploration of the thematic areas of the cities and the connections between them. Nonetheless, it is possible to spot some instances in which the interpretation is ambiguous, weak or unexpected.

In order to limit this problem, WEAT and SWEAT have been tested.

WEAT vs SWEAT After an attempt of creating some models from city-based sub-corpora, the SWEAT result were not significant, due to the size of the texts, not enough to generate a decent working model.

The final choice fell on WEAT

### Step 3 - WEAT usage

Two different procedures have been developed. For both of them, the problem is represented by defining the **context** through the set of terms A and B on the basis of the topic that wanted to be explored.

1

#### **Topic**

Custom version of WEAT called **TWEAT** (T stands for Topic). It works by combining a list of topics to the two lists of attributes. Its goal is to distinguish between negative and positive perception on something

2

#### **Analogies**

It works by exploiting analogies, in order to obtain sets of terms related to the same topic but from two opposite points of view, which don't necessarily are "negative" and "positive".

# **WEAT Disambiguation** - *Topic*

Definition of the most polarizing attributes, starting from a larger list

POS = [useful, important, benefit, solution, best, better]

**NEG** = [worse, terrible, horrible, awful, disgusting, dreadful]

Definition of X, Y, A, B

- $X \rightarrow 1^{st}$  set of cities
- $Y \rightarrow 2^{nd}$  set of cities
- A  $\rightarrow$  combination of POS with W<sub>T</sub>
- B  $\rightarrow$  combination of NEG with W<sub>T</sub>

where  $W_T$  is a list of Words about a topic T

Run classical WEAT, with X, Y, A, B

**Culture** (America Latina vs European)

Music → Tribal vs Noble

**X** = [brasilia, sao\_paulo, rio\_janeiro, buenos\_aires, santiago chile]

**Y** = [rome, paris, vienna, munich, saint\_petersburg]

**A** = [band, dance, drumming, percussion, song, orchestra, jazz, drum, piano, guitar]

**B** = [harmonium, piano, violin, singing, oboe, orchestra, pianoforte, sing, clavichord, bagpipe]

**Effect size** = 1.812

P-value = 0.0

**History** (Colonizers vs Colonies)

 $\textbf{Colonialism} \rightarrow \textbf{Invader vs Oppressed}$ 

X = [lisbon, porto, madrid]

Y = [sao\_paulo, rio\_janeiro, santiago]

A = [colonizer, invading, colonization, imperialist, colonialist, invasion, imperialism, colonized, neo\_colonialism, conqueror]

**B** = [oppression, oppressor, oppress, marginalized, neo\_colonialism, colonized, patriarchy, apartheid, injustice, subjugate]

Effect size = 1.258

P-value = 0.0

### **WEAT Disambiguation** - Comparison

#### Method 1 - With Topic

As before, supervised methods are more specific, but this can be restrictive

Results are not as good as expected: topics don't disambiguate that much, even though they manage to polarize more than when they are not used

#### Method 2 - With Analogies

- As before, unsupervised methods are more powerful but less controllable. Some results may not be fully correlated to the sets A and B under survey
- Consequently, the measures provided can't be taken as accurate and truthful but can be interpreted with a more stereotyped key

### WORKFLOW

- 3.2. Method 1 Topic
- 3.3. Method 2 Analogy
- 3.4. Results comparison

#### 1. Conclusion

- 4.1. Final results and stereotypes analysis
- 4.2. Limitations and future research

### **Conclusions**

1

How are the different cities in the world perceived? What are the terms/topics most associated with them?

The gathered words manage to picture the major characteristics about cities, in terms of different topics. Wordclouds show that:

- → some cities are strongly related to one or few topic in their words:
  - Food in **Bologna:** [scalopped\_potato, mortadella, eggplant\_parmesan, home\_baked, manicotti, tortellini ... ]
  - Culture in Vienna: [beethoven, mozart, brahms, schubert, waltz, deutsche\_grammophon]
  - Environment in **Copenhagen:** [kyoto, carbon\_emission, ipcc, ghg\_emission, unep, marpol]
  - Politics and Economy in **Moscow:** [kremlin, gorbachev, putin, soviet\_union, kgb, espionage, primakov]
- → on the other hand, other cities whom topics are heterogeneous but still well correlated:
  - Sociality and Environment in **Beijing:** [economic\_growth, export\_led, air\_pollution, emissions, devalue currency ...]
  - Education, Culture and Sociality in **New York:** [college, 20th\_century\_art, metropolitan\_museum, paul\_krugman ..]
  - Tourism and Sociality in **Dubai**: [stock\_market, emerging\_market, mini\_vacation, golfing, undiplomatic ...]
  - Crime and Drugs in **Bogotà**: [cocaine, illicit\_drug, alcohol, kidnapping, drug\_trafficking, psychoactive\_substance ...]

### **Conclusions**

2

How is the world described in collective imagination, in terms of topics?

The network graph allows to make some general considerations:

- → In the Crime topic, Middle East, Central Africa and Latin America stand out.
- → The History topic creates strong interconnections in Europe, we note the influence of the UK in North America and Australia and the influence of Spain and Portugal in Latin America (the latter is also visible in the Culture and Food topics).
- → The *Education* topic denotes a large gap between the **Northern** and **Southern** hemisphere of the world, with the exception of **Australia**.
- → The topic *Environment* is present and strongly connects *Northern Europe*, *Latin America*, *China* and *India*.
- → From the *Culture* topic emerges once again a strong homogeneity in *Europe* linked to everything (classical music and different artistic currents) and a strong connection between the cities of *South America*.

### **Conclusions**

Are there any polarizations (positive/negative) regarding to these characteristics? Are common stereotypes confirmed?

There are obviously different points of view in interpreting the topics related to cities. With the final step we tried to disambiguate them, even where cities look strongly connected.

→ Difference in meaning regarding to the Environment topic in Northern Europe where words are commonly related to danger and climate protection activities, compared to South America or Indian cities where are associated to words more aimed at the causes of environment.

Additionally is possible to use WEAT to highlight any stereotype of the collective imaginary

- → Comparing food between meat and fish recipes, we can observe that meat ones are more associated to italian places instead of seafood being more present in oriental cities.
- → Opera and classical music is best connected to european countries rather than brazilian cities, in which drums and tribal rhythms are majorly present.

## Considerations, limits and future developments

Models in different years (evolution of terms and associated topics)

Hodels in different years (evolution of terms and associated topics)

Models in specific corpus (representation of cities in films or news)

Choice of initial words in supervised method

Strong bias on the specificity of the selected words

Possibility to exploit the model to extend the word list starting from an initial set

## Considerations, limits and future developments

Research for more targeted analogies or Less bias, more noise Unsupervised compare them in a pre-compiled set analogies results DB-SCAN not optimized Dedicated clustering to highlight specific management subtopics Possible use of SWEAT on corpus from Topic WEAT ineffective different cities Use of WEAT for disambiguation and Non-intuitive analogies Composition of sets A and B supervised stereotypes with domain-specific terms.
